

# The uncertainties in surface altimetry of space-borne lidar measurements caused by unknown size (and shape) of ice particles

Alexander Marshak (GSFC)

Yuekui Yang (UMBC)

Warren Wiscombe (GSFC)

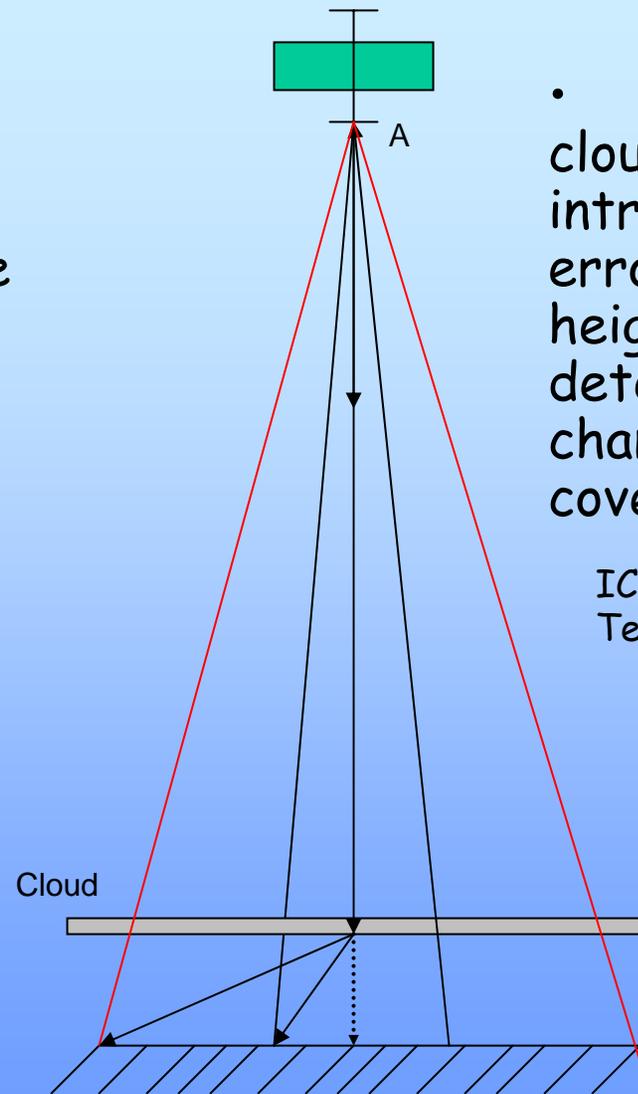

# Motivation

- "... forward scattering of the laser light from clouds and aerosols increases the path length, thus making the surface appear farther from the satellite."
- The residual bias "imposed by undetected cloud scattering is at the decimeter, not centimeter level."

ICESat II workshop report, 2007

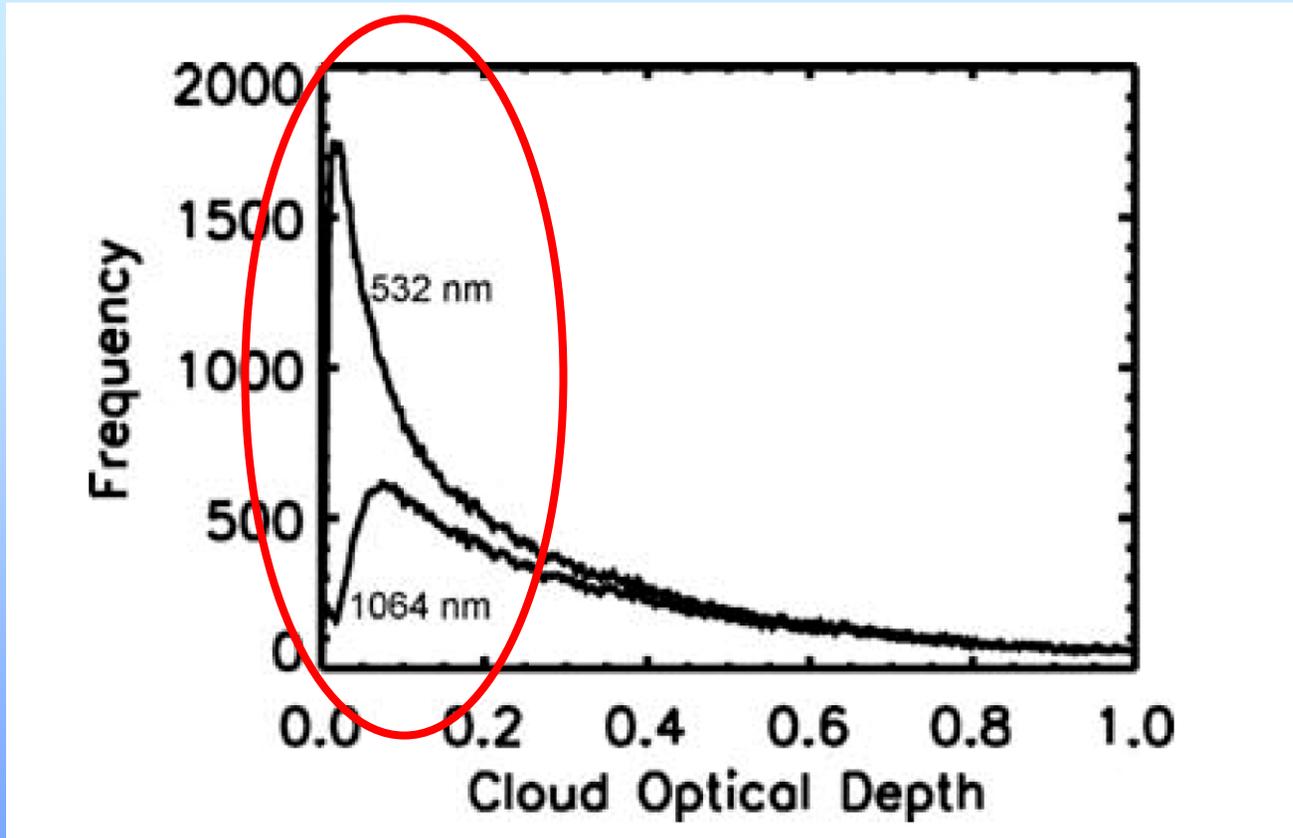

- "A bias from cloud scattering introduces an error to surface height *change* detection due to changes in cloud cover."

ICESat II Science Team report, 2008

# Clouds missed by the 1064 nm channel

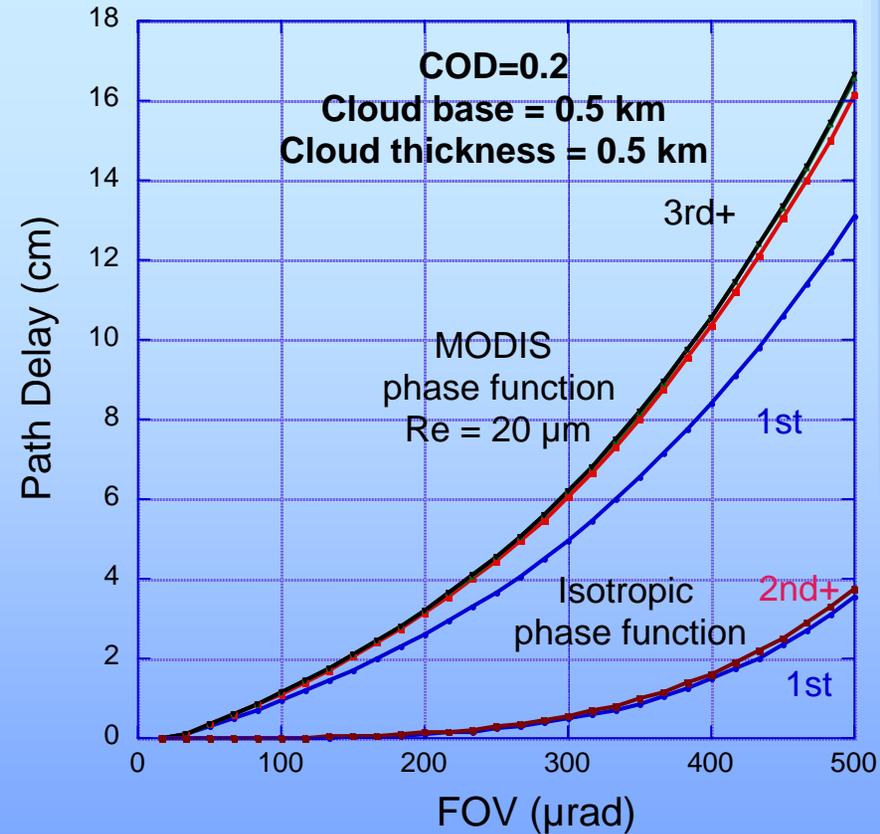

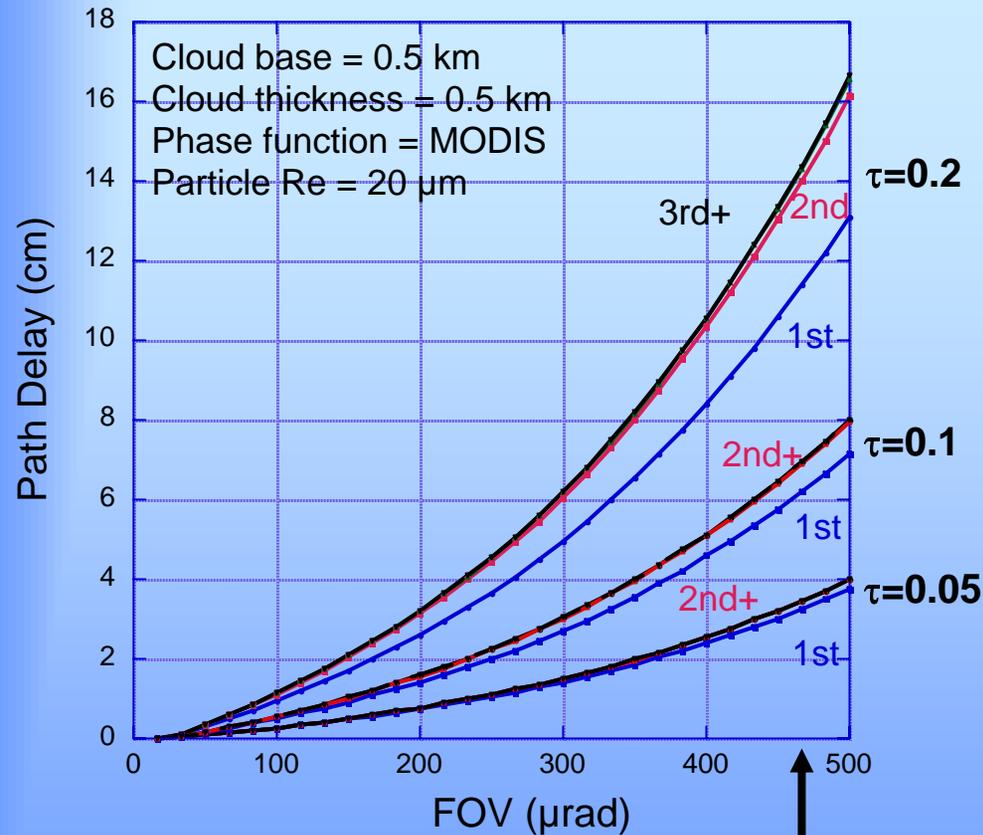

(from Spinhirne et al., 2005)

The relative frequency of *COD* retrieved from the 532-nm channel together with clouds detected by the 1064-nm channel.

# Scattering order: forward-scattering and isotropic phase functions

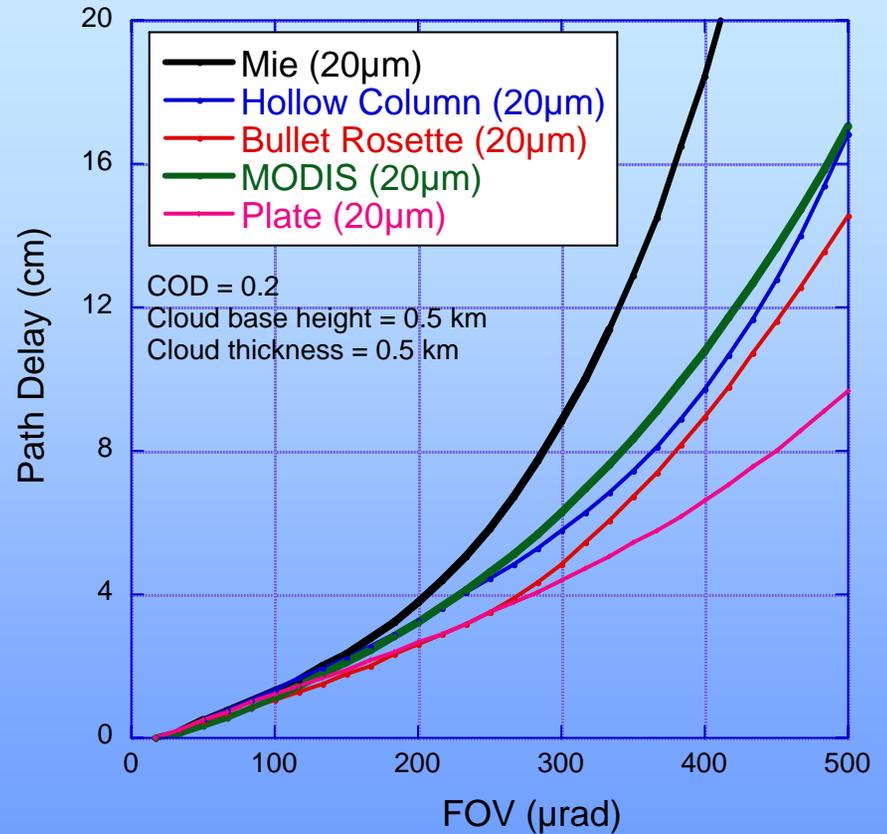

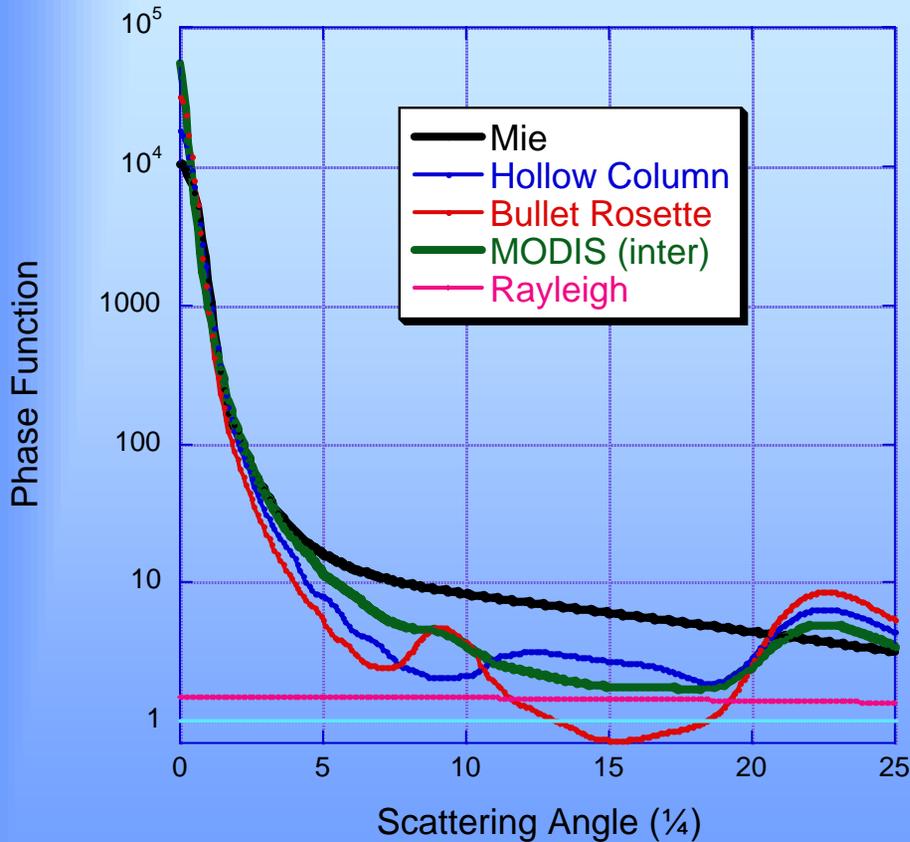

Different COD

The current  
GLAS FOV:  
 $485 \mu rad = 285 m$

Forward-scattering  
and isotropic phase  
functions

# Effect of particle shape on the range delay

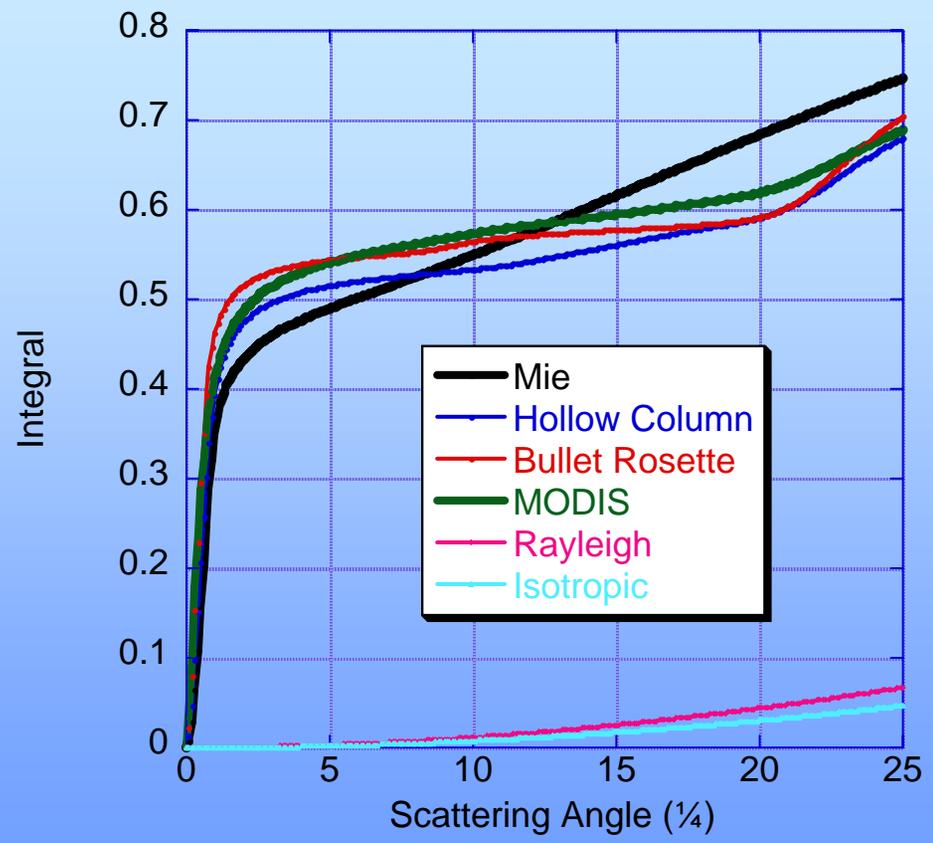

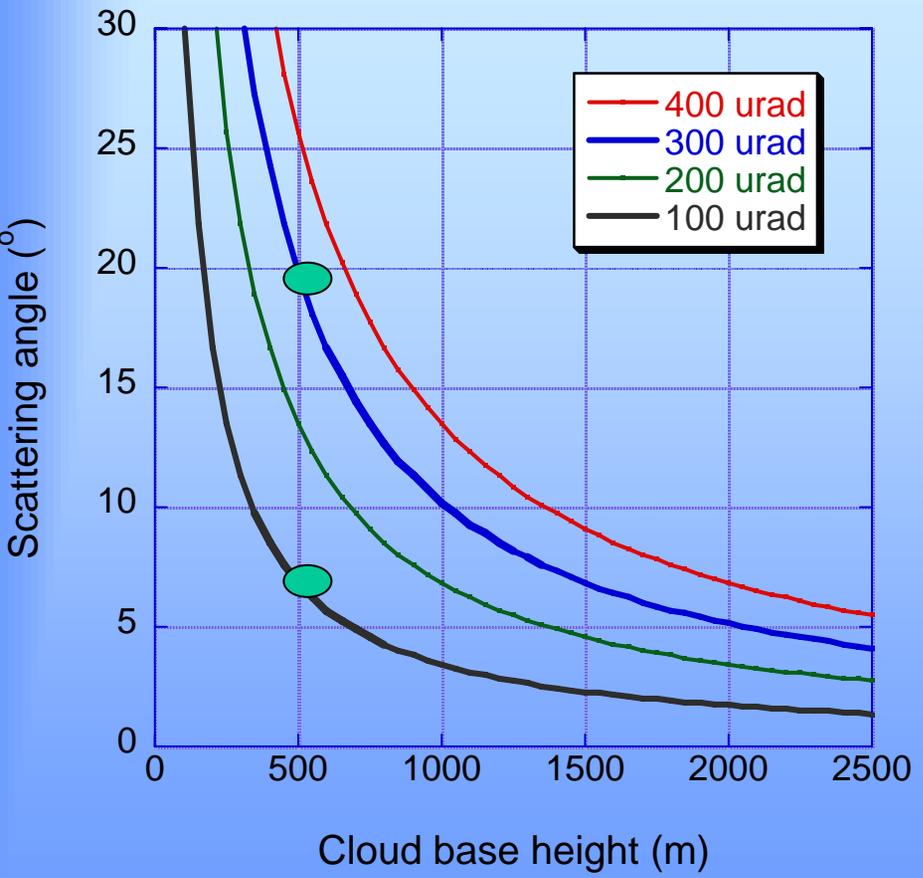

for 100  $\mu$ rad 1.0-1.5 cm; for 300  $\mu$ rad 4-6 cm

# What scattering angles need to be accounted for as a function of FOV and CBH

$$p(\theta) = \frac{1}{2} \int_0^\theta P(\theta') \sin \theta' d\theta'$$

Scattering Angle inside FOV

If clouds are between 0.5 and 1 km, for FOV=100μrad θ<7° is important while for FOV=300μrad θ<20°

# Blowing Snow

## Why should we care about blowing snow?

# The uncertainties in range delay for FOV=160 $\mu$ rad

Size and shape of ice crystals varies

# Expected path delay

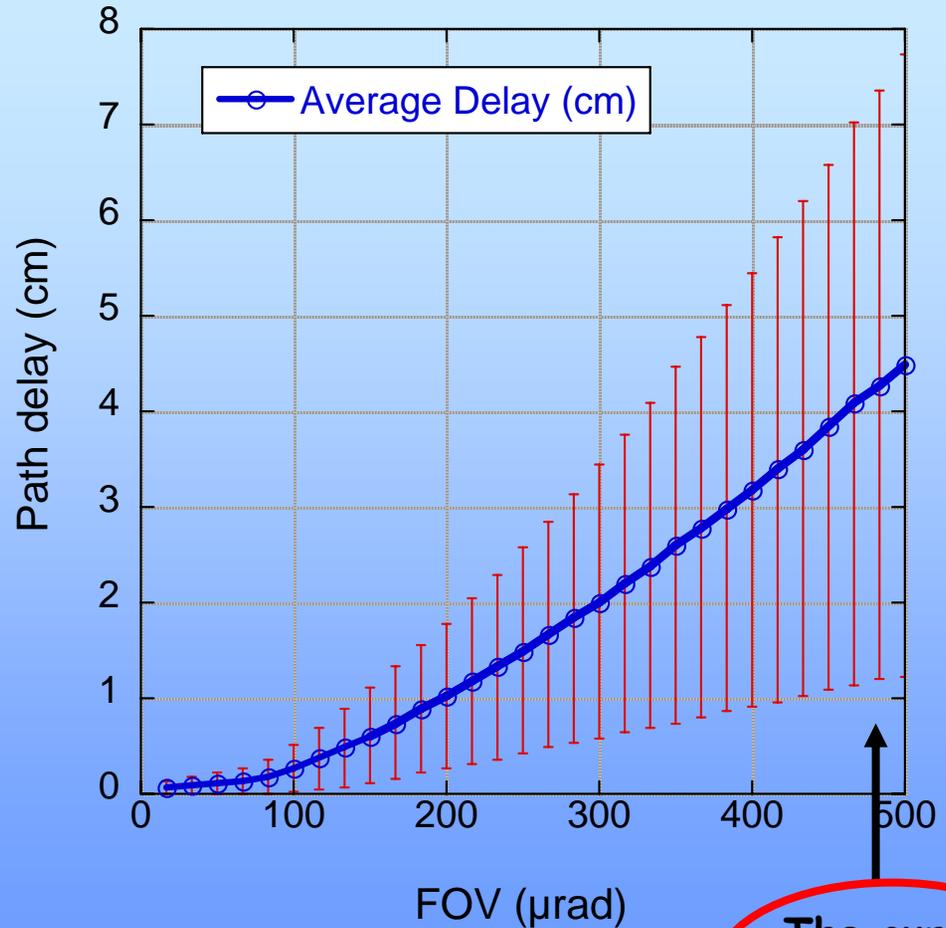

$$I(\Delta\psi) = \iiint p_1(h_b, \tau) p_2(\tau) p_3(r_{eff}) L(h_b, \tau, r_{eff}; \Delta\psi) dr_{eff} d\tau dh_b$$

•  $p_1(h_b, \tau)$  is the pdf of cloud base  $h_b$  and COD  $\tau$ ;

•  $p_2(\tau)$  is the pdf of COD  $\tau$  undetected by the 1064-nm channel;

•  $p_3(r_{eff})$  is the pdf of effective radius  $r_{eff}$  for thin transparent clouds;

•  $L(h_b, \tau, r_{eff}; \Delta\psi)$  is the MC calculated range delay as a function of  $\Delta\psi$ .

# Particle shape at South Pole Station

from Lawson et al., JAM 06

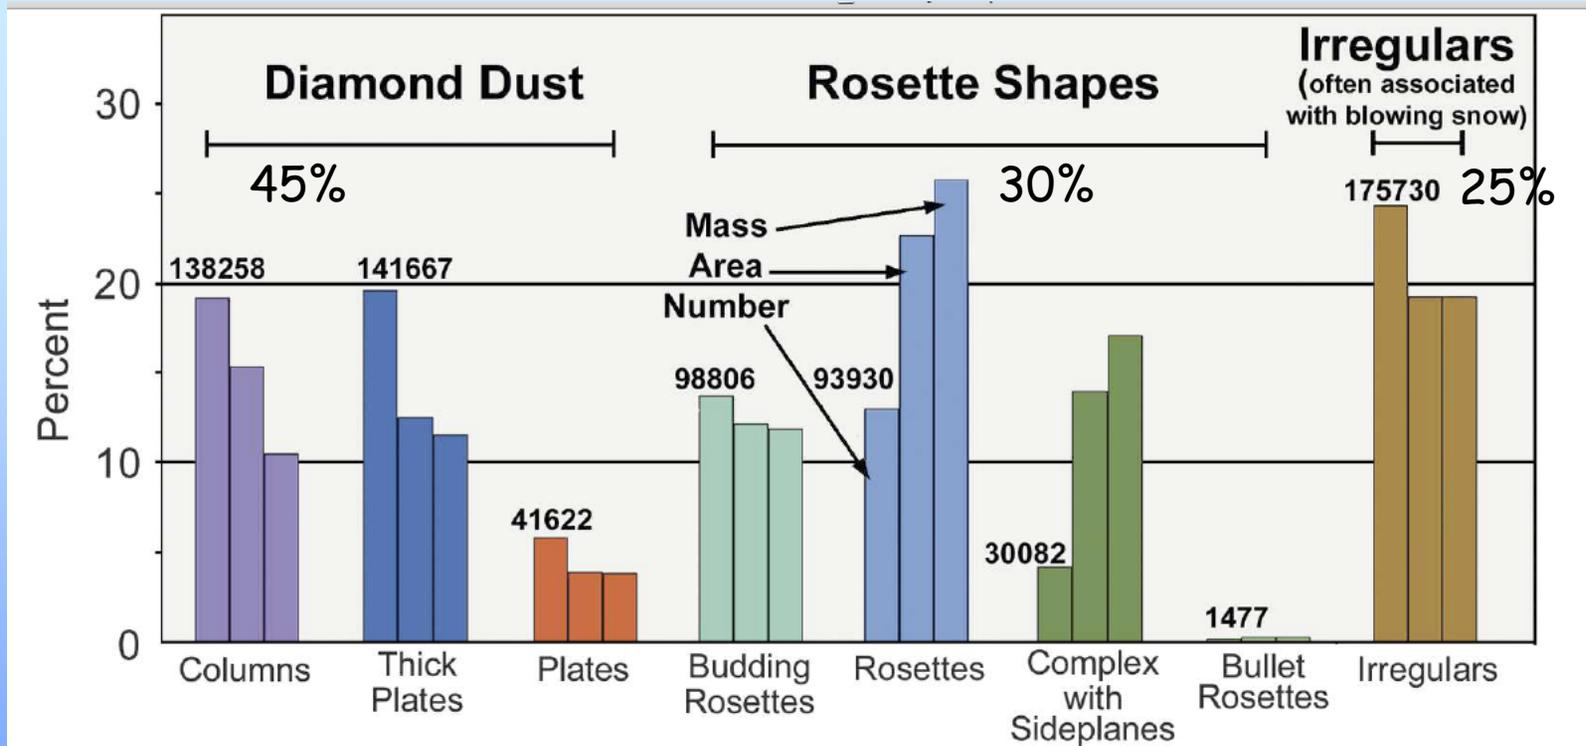

FIG. 5. Histogram of ice crystal habits observed at SPS during the period of 1-8 Feb 2001. The percentage weighted by concentration, area, and mass is shown for each habit category. Columns, thick plates/short columns, and plates are associated with diamond dust. Budding rosettes, rosettes, and complex with side planes are associates with rosette shapes. The total number of crystals of each habit is shown above its category. The total number of ice crystals categorized is 721 572.

# Particle shape and size at South Pole Station

from Lawson et al., JAM 06

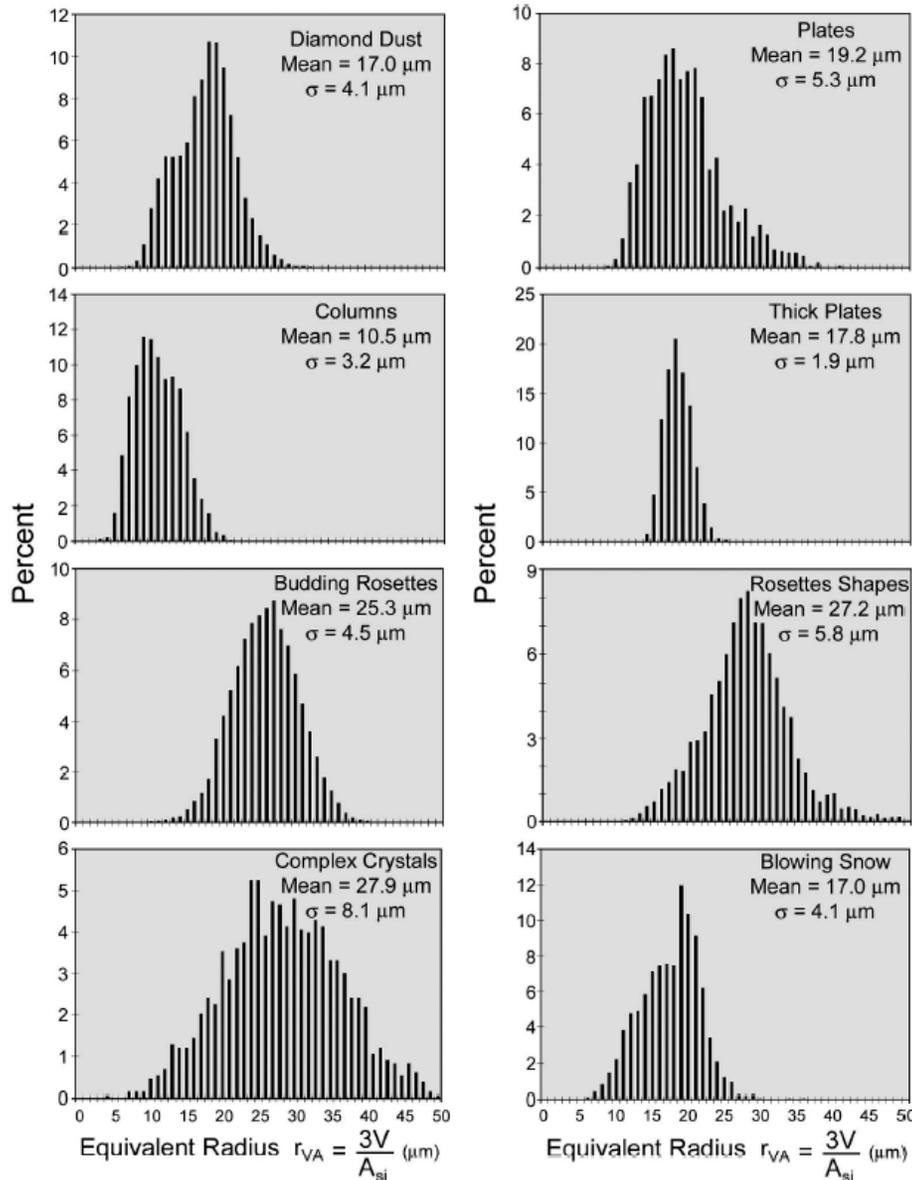

FIG. 11. Histograms showing size distributions of various ice crystal habits as a function of equivalent radius.

# Particle size and shape for thin polar clouds

- *in-situ* measurements of droplet size distribution are rare in polar regions, esp. in Antarctica (there are some *ground-based* measurements, though).
- the differences between cirrus clouds in the tropics and in the polar regions are poorly understood;
- ice particle size strongly correlates with T; at least for tropical clouds, cold very thin clouds may have very small ice crystals;
- problems with small ice crystals ( $D < 50 \mu\text{m}$ ): shattering of large particles overestimates concentration of small ice crystals;
- remote sensing retrievals have large uncertainties, esp. for very thin clouds;
- CALIPSO's Infrared Imaging Radiometer (IIR) retrieves  $R_{\text{eff}}$  but not yet available. Its accuracy over polar region clouds is unknown;
- Lidar/Radar/IR retrievals of particle size is, perhaps, the most promising;

# Data

- ICESat
- MODIS
- CALIPSO

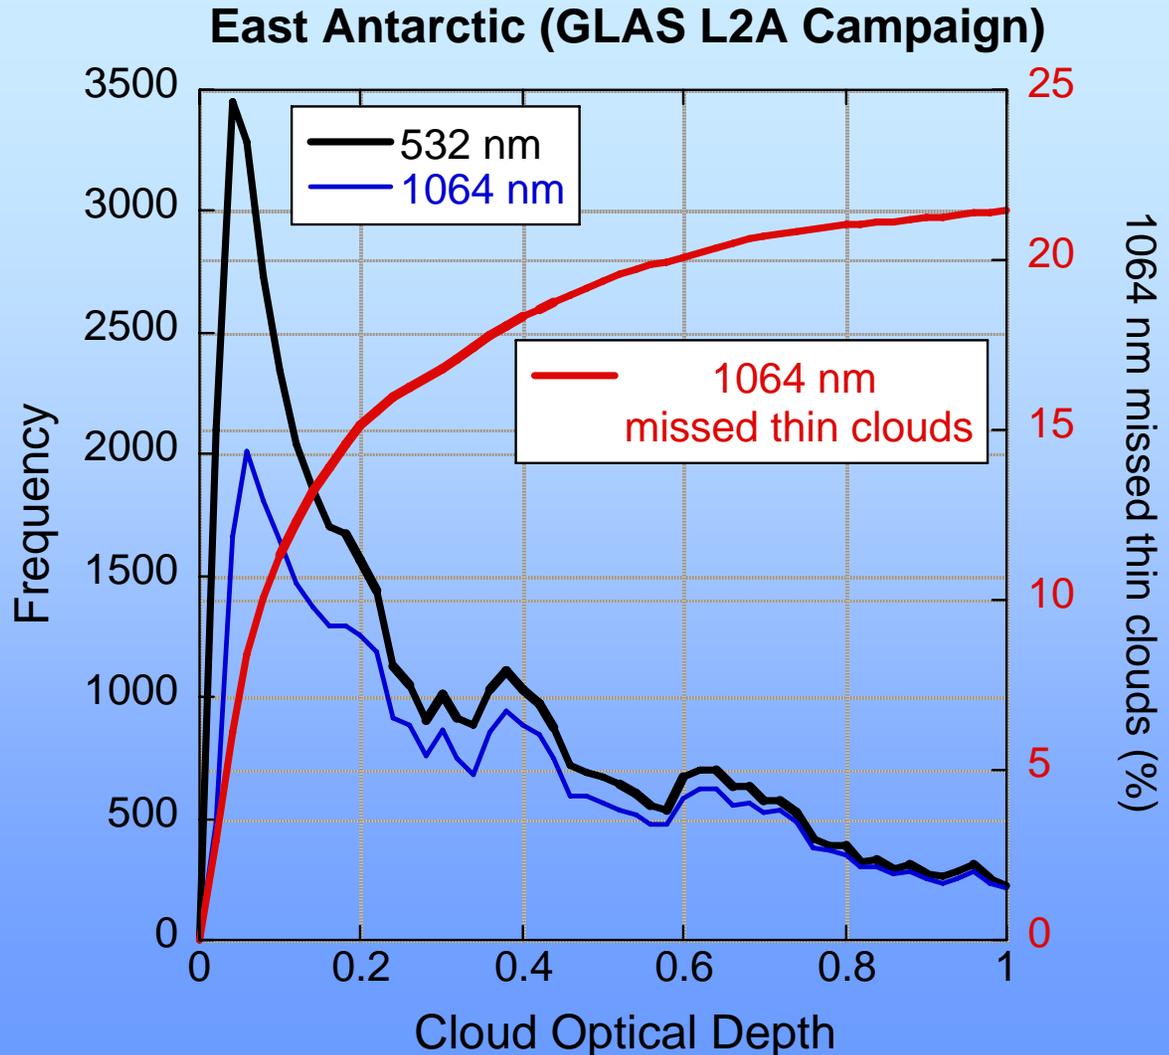

for Greenland, East and West Antarctica

# GLAS: clouds missed by the 1064-nm channel

	CF(%)	Thin(%)	Missed(%)
EA:	34	56	22
WA:	59	55	11
GR:	60	42	31

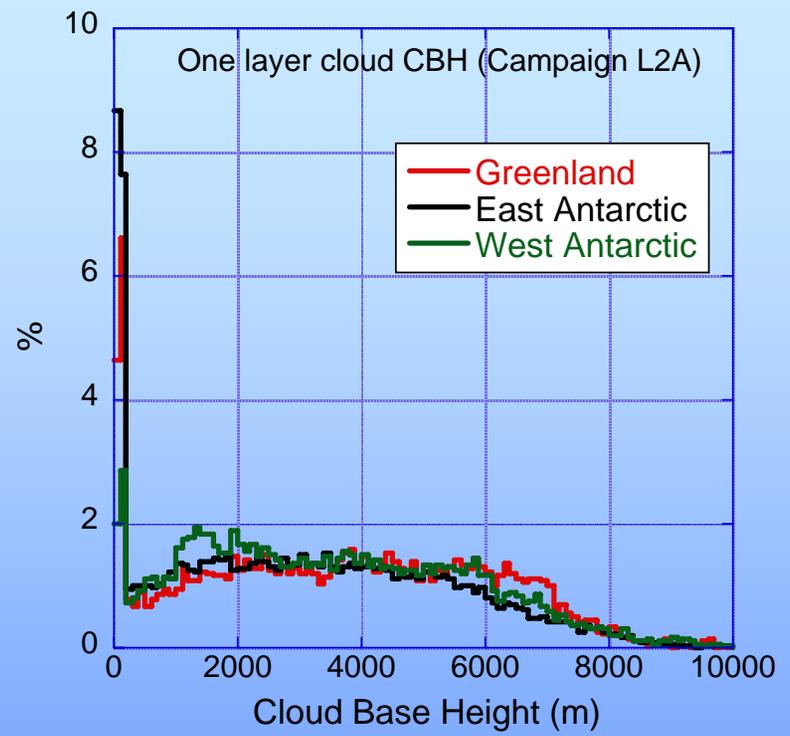

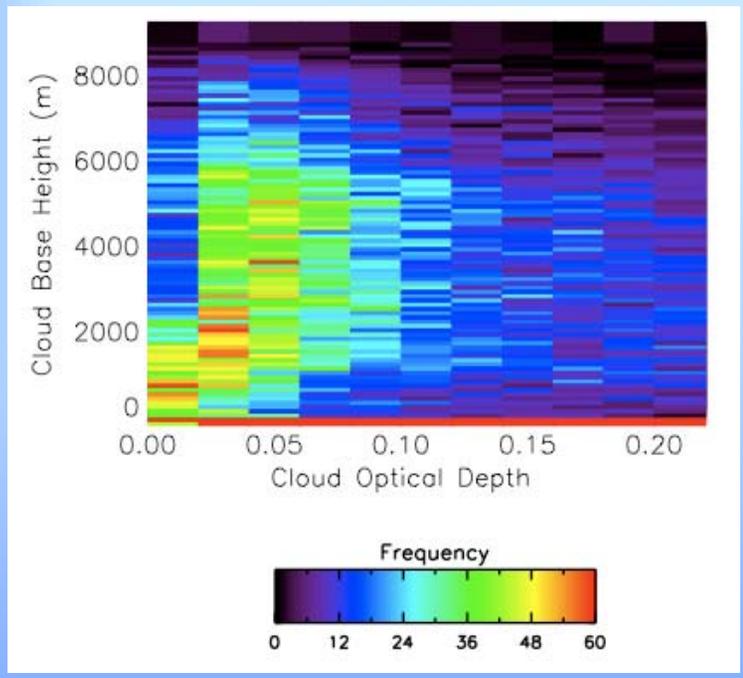

The relative frequency of COD retrieved from the 532-nm channel together with clouds detected by the 1064-nm channel. Red curve is the cumulative distribution function of thin transparent clouds missed by the 1064-nm channel.

# GLAS data: CBH vs COD

Based on GLAS L2a campaign (Oct. 2003)

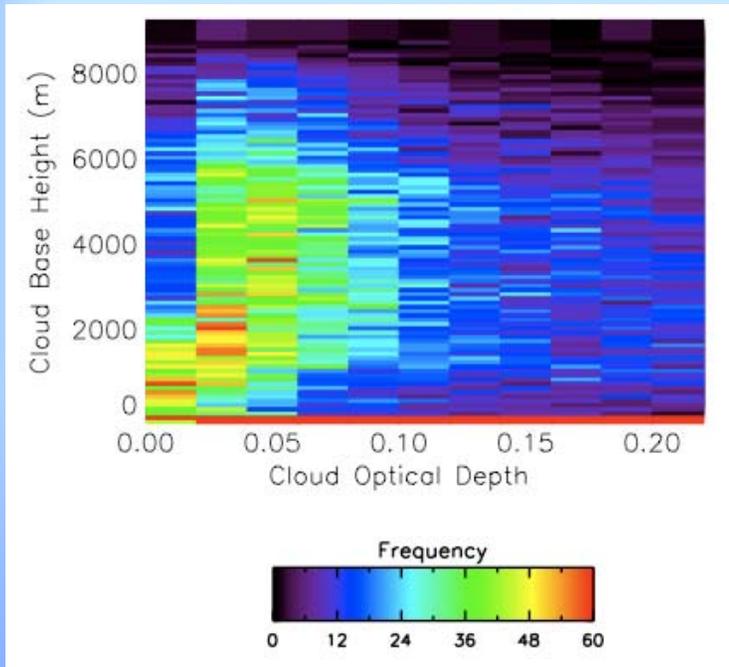

The pdf of CBH and COD for East Antarctica with  $COD < 0.2$ . 'Warm' colors mean high probability while 'cold' colors mean low.

The distribution of CBH for the one layer clouds  $COD < 0.2$

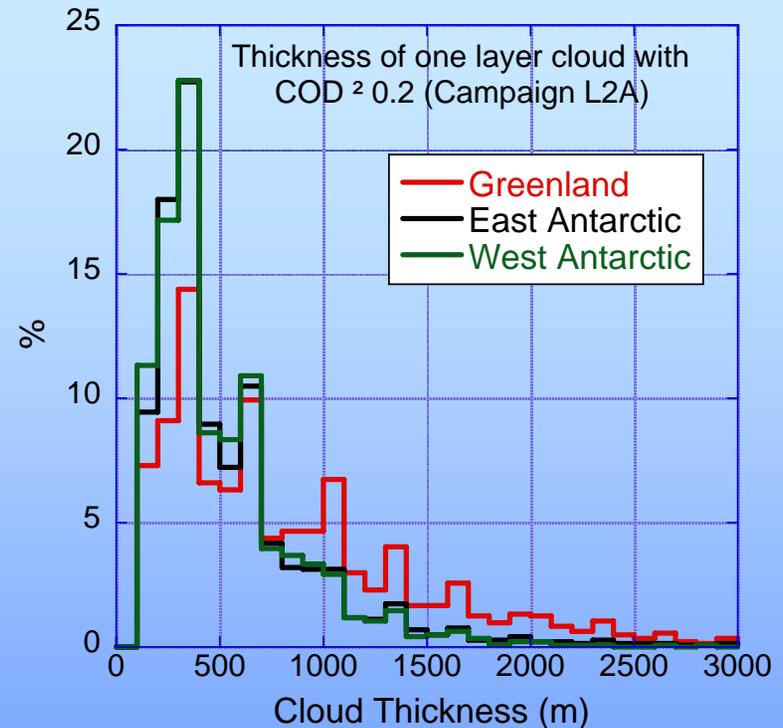

# GLAS data: CBH vs COD

Based on GLAS L2a campaign (Oct. 2003)

The pdf of CBH and COD for East Antarctica with  $COD < 0.2$ . 'Warm' colors mean high probability while 'cold' colors mean low.

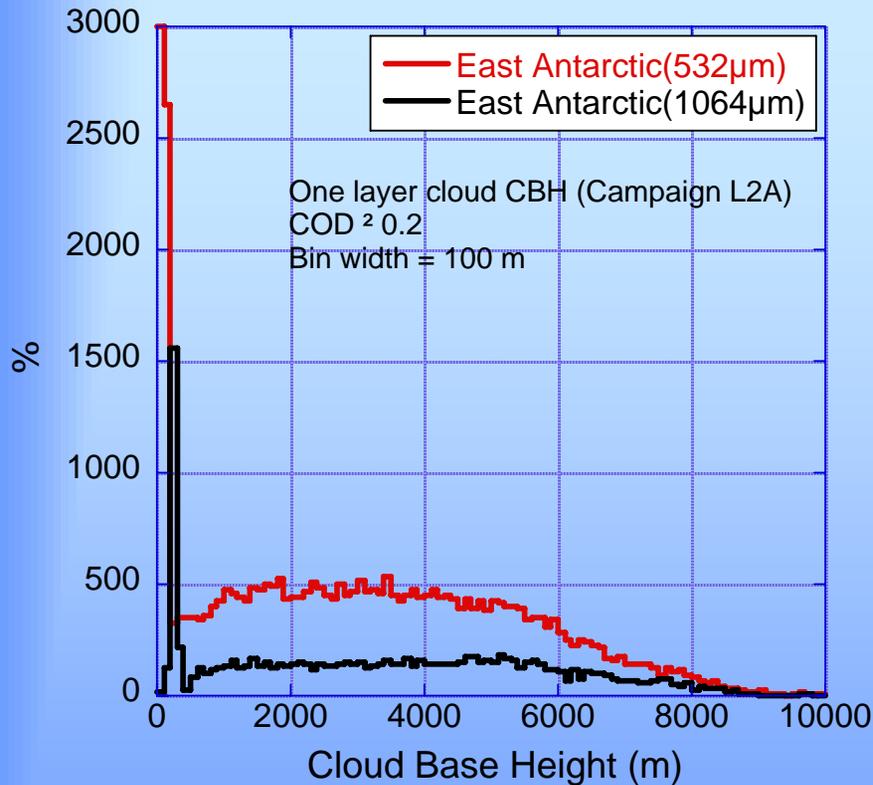

The distribution of cloud thickness for the one layer clouds  $COD < 0.2$

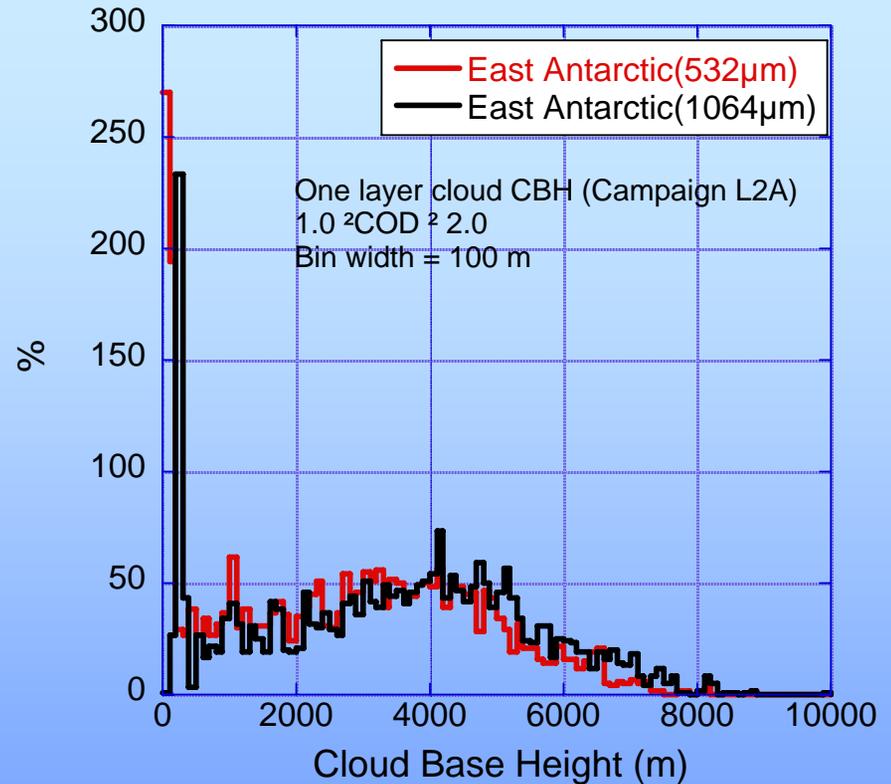

# GLAS data: CBH 532nm vs 1064nm

Based on GLAS L2a campaign (Oct. 2003)

$COD \leq 0.2$

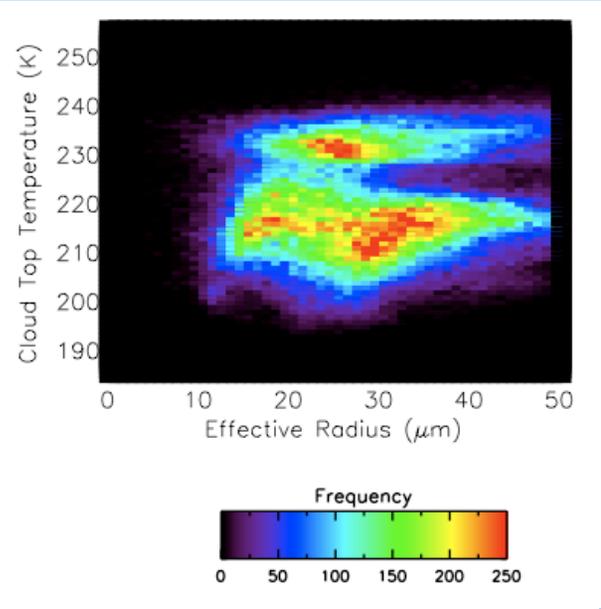

$1 \leq COD \leq 2$

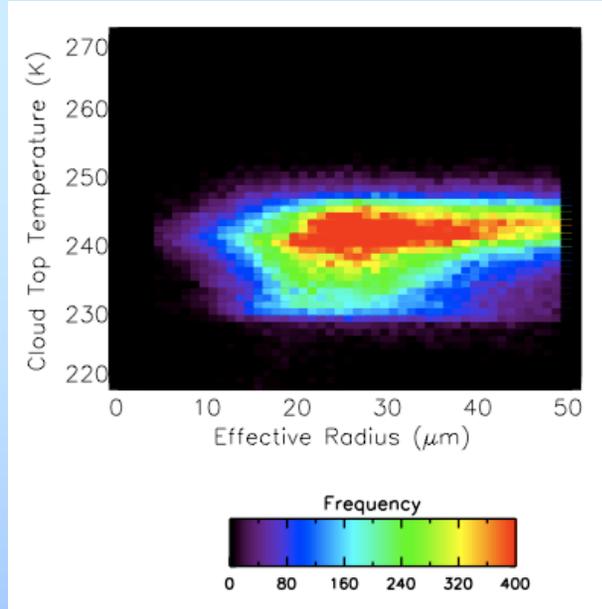

# MODIS data: $R_{eff}$ vs CTT

# Conclusions

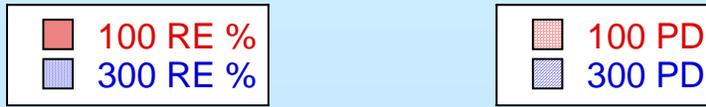

- Properties of the forward-scattering phase function peak are the greatest unknown;
- Existing remote-sensing data on ice particle size have large uncertainties; not much ground-based measurements and rare in-situ observations;
- Very preliminary calculations based on ICESat, CALIPSO and MODIS data estimate range delay as  $5 \pm 2$  cm for  $FOV = 300 \mu\text{rad}$  and  $0.7 \pm 0.5$  cm for  $FOV = 100 \mu\text{rad}$ ;
- To reduce the uncertainties we suggest
  - to measure the forward scattering properties directly
  - to use two FOVs
- The returned energy from one- and two-scatterings order photons can be well approximated by simple analytical expressions based on RT

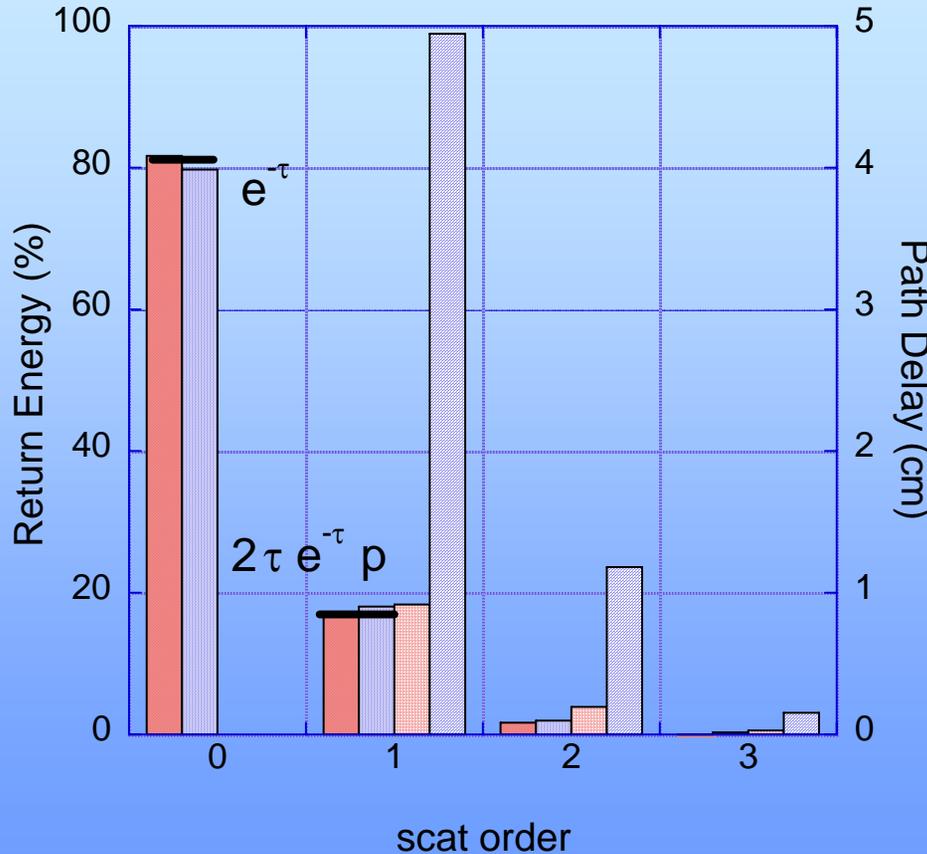

# Back-up slides

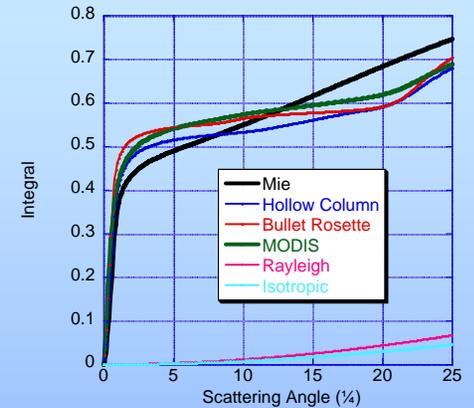

# Scattering order: returned energy and path delay for two FOVs (100 & 300 $\mu\text{rad}$ )

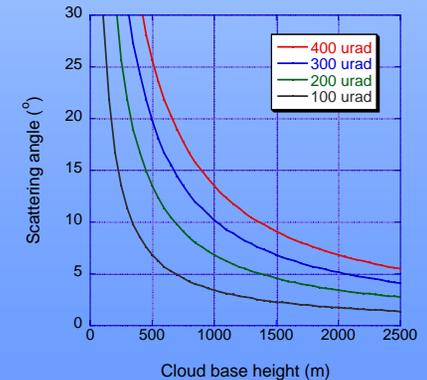

COD=0.2

$$p(\theta) = \frac{1}{2} \int_0^\theta P(\theta') \sin \theta' d\theta'$$

Scattering angle inside FOV

# New suggestions

- Direct measurements of forward scattering properties
- Two-FOVs system

# Dual FOV

(1) with 2FOVs we can solve the problem of undetected clouds **once and for all.**

(2) with 2FOVs we would be able to **correct altimetry data contaminated by clouds.**
